TITLE: Method and system for defining and discovering proxy functionality on a distributed audio video network

# Detailed Description Text (18):

FIG. 3A is a block diagram of memory space referred to as a configuration ROM 302, which is located within each node (e.g., TV 11, VCR 12, set-top-box 13, etc.) of network 5 of FIG. 1. It should be appreciated that configuration ROM 302 of the present invention is defined by the IEEE 1212 specification, which is well known by those of ordinary skill in the art and is the foundation technology of the IEEE 1394 serial bus specification. One embodiment of configuration ROM 302 is a 64 bit memory space that is divided into two different subsections. One subsection contains the upper 16 bits of address space that are used for storing the identification (ID) of a node, which includes its physical identification (phyID) 304. The other subsection within configuration ROM 302 contains the remaining 48 bits of address space that are used for storing other configuration ROM data structures 306 pertaining to the specific node, e.g., its Global Unique Identification (GUID) value. In this manner, an IEEE 1394 serial bus network of the present invention is a memory mapped bus network. It should be appreciated that a proxy data structure 330 is typically stored within the 48 bits of address space along with the other data structures 306 of configuration ROM 302, in accordance with the present invention. The proxy data structure 330 is described in more detail below with reference to FIGS. 3C and 3D. It should be further appreciated that there are many other embodiments of the configuration ROM 302 in accordance with the present invention. For example, the configuration ROM 302 can be implemented using RAM, static RAM, dynamic RAM, programmable ROM, flash memory, EPROM, EEPROM, or any other memory device.

Detailed Description Text (21):
The proxy tag 332 of FIG. 3C, in accordance with the present invention, is a recognizable tag to other nodes of network 5 indicating that proxy device 13 is a proxy for a particular node (e.g., VCR 12). It should be appreciated that proxy tag 332 should be defined within the IEEE 1212r specification, in accordance with the present invention. In this manner, all other consumer electronic devices that are coupled together by an IEEE 1394 serial bus will, by definition, recognize proxy tag 332 when they search the configuration ROM of proxy device 13, regardless of whatever higher level protocols (e.g., AV/C, HAVi, etc.) they support. The length 334 indicates the amount of bytes that correspond to the proxy identifier 336.

## Detailed Description Text (31):

FIG. 5 is a flowchart illustrating steps of a process 500 for establishing a proxy consumer electronic media device as a proxy for other consumer electronic media devices in accordance with one embodiment of the present invention. It should be appreciated that process 500 is one embodiment of step 404 of FIGS. 4A and 4B, in accordance with the present invention. Process 500 is realized as program code stored within computer readable memory units of a proxy consumer electronic media device and other consumer electronic media devices of network 5. Process 500 begins at step 502 and at step 504, the proxy device discovers a consumer electronic media <u>device</u> which is coupled to the IEEE 1394 <u>serial bus</u>. This process utilizes well known IEEE 1394 communication protocol mechanisms. At step 506, the proxy device determines the functional capabilities of the located consumer electronic media device. One method in accordance with the present invention for the proxy device to perform step 506 is to read all of the configuration ROM within the located consumer electronic media  $\underline{\text{device}}$ , which is a well known IEEE 1212 communication protocol mechanism.

## ABSTRACT:

A method and system for defining and discovering proxy functionality on a distributed audio video network. The present invention operates within a network of consumer electronic media devices (e.g., television, set-top-box, video cassette recorder, compact disc device, personal computer system, etc.) that are coupled together using the IEEE 1394 serial communication standard. Specifically, the present invention enables a consumer electronic media device having increased functionality to act as a proxy device for other consumer electronic media devices. As such, the proxy device is able to provide a wide variety of advantageous proxy services for other consumer electronic media devices thereby increasing their original capabilities. For instance, the proxy device can act as a translator between two devices thereby enabling them to communicate. Additionally, the proxy device can enable Home Audio Video Interoperability (HAVi) devices to have greater control over non-HAVi devices. Moreover, the proxy device can extend the existing functionality of devices as well as provide new functionality for them. Furthermore, the proxy device can act as a command arbitrator for particular devices. Also, the proxy device can act as a proxy for all or a portion of the functionality of a device. It is appreciated that these are only examples of the possible advantageous proxy services that the proxy device can provide for other devices in accordance with the present invention.

## ABSTRACT:

A topology map for a digital system is generated and displayed on a display device to indicate the various components which make up the system. The various components are indicated using icons each of which represent a respective one of the components. A user specifies a source device and a receive device by manipulating the corresponding icons so as to cause a data transfer between the source device and the receive device. The data transfer may include the transfer of video data, audio data, or both. In a preferred embodiment, the digital network corresponds to the IEEE 1394 Serial Bus Standard.

DOCUMENT-IDENTIFIER: US 6643714 B1

TITLE: Modification and use of configuration memory used during operation of a serial bus

## Brief Summary Text (6):

The configuration memory of a given <u>node</u> provides, in part, a description of the functional capabilities of that <u>node</u>. The configuration memory for each <u>node</u> residing on the <u>serial bus</u> is exposed to all other <u>nodes</u>. During a configuration process, other <u>nodes</u> access each <u>node's</u> configuration memory (a process often referred to as "enumerating") in order to determine the proper system configuration. Thus, one function of the configuration memory of a given <u>node</u> is to instruct other <u>nodes</u> as to the given <u>node's</u> functional capabilities, thereby allowing the other <u>nodes</u> to determine which <u>device</u> drivers to load. As known in the art, for a general computer system having a number of <u>devices</u>, <u>each device</u> has an associated driver that, among other functions, configures the <u>device</u> and allows the <u>device</u> to be operable within the overall system. Drivers are typically software instructions that can be loaded into the computer's memory and, when executed, will communicate with the <u>device</u> to properly configure the <u>device</u> for operation. The driver may initialize the <u>device</u> so that the <u>device</u> can function and the driver may also allow the <u>device</u> to communicate within the overall system.

# Brief Summary Text (10):

In one embodiment of the present, invention, any PC coupled via an IEEE 1394 standard compliant serial bus to one or more 1394-compliant devices could be used to emulate the functionality of virtually any 1394-compliant device. In turn, this emulation capability allows developers to simulate device/peripheral functionality during development. In another embodiment of the present invention, peripherals coupled to the "emulating" PC but not otherwise available via the serial bus can be exposed to other devices coupled to the PC via the serial bus. For example, a PC having a Digital Video Disc (DVD) drive coupled thereto can emulate to other 1394 nodes that it is a DVD drive, thereby allowing the other 1394 nodes to access the DVD drive functionality.

# Drawing Description Text (3):

FIG. 2 is a schematic block diagram of a system of <u>devices</u> and <u>corresponding nodes</u> coupled together via a serial bus;

# Detailed Description Text (9):

Procedures of the present invention to be described below can operate within the environment of the computer 100 shown in FIG. 1. Although the present invention is generally applicable to a computer operating in accordance with the IEEE 1394 standard, the present invention is applicable to any computer system that implements the Control and Status Registers (CSR) configuration ROM architecture described in the ISO/IEC 13213 (ANSI/IEEE 1212) CSR Architecture Specification. An exemplary system of devices 200 communicating via a serial bus, to which system the present invention may be beneficially applied, is illustrated in FIG. 2.

# Detailed Description Text (10):

The system 200 comprises several <u>devices</u> including a computer 201 (such as the computer 100 of FIG. 1), a printer 202, a digital camera 203, a scanner 204, a digital VCR 205 and a CD-ROM 206. As shown, the <u>devices</u> 201-206 are coupled to each other via multiple interconnections 222-226. Each of the interconnections 222-226 is

preferably constructed in accordance with the IEEE 1394 standard and includes a first differential signal pair for conducting a first signal, a second differential signal pair for conducting a second signal, and a pair of power lines. Although specific devices are shown in FIG. 2, those having ordinary skill in the art will recognize that a wide variety of electrical/electronic devices could be coupled together in this manner using a similarly wide variety of interconnections. Although not shown, the computer 201 may include one or more devices that are normally not functionally available to the other devices 202-206. Collectively, the interconnections 222-226 constitute the cabling of the serial bus and a plurality of nodes 211-216 implement the functionality of the serial bus. Each of the devices of the computer system 200 is coupled to a node of the serial bus. In general, the device to which a node is coupled acts as the "local host" for that node. For example, the computer 201 is the local host for the computer node 211; the printer 202 is the local host for the printer node 212; the digital camera 203 is the local host for the digital camera node 213; the scanner 204 is the local host for the scanner  $\underline{\text{node}}$  214; the digital VCR 205 is the local host for the digital VCR node 215; and the CD-ROM 206 is the local host for the CD-ROM node 216. It is not necessary for every node to have a local host, nor is it necessary that the local host always be powered.

## Detailed Description Text (12):

Each of the nodes 211-216 also provides an address space which can be directly mapped to one or more units. A unit is a logical entity (for example, a disk controller) which corresponds to unique input/output (I/O) driver software. A unit may be defined by a unit architecture that defines the format and function of the unit's software visible registers. Within a unit there may be multiple subunits, which can be accessed through independent control registers or uniquely addressed DMA-command sequences. The logical organization of nodes and units is further illustrated in FIG. 3, where a module 301 comprising a plurality of nodes 303-305 is shown. A module is a physical device, coupled to a serial bus 312, having one or more nodes. Each of the nodes may comprise one or more units 307-310. The implementation and operation of the nodes is well known in the art.

## Detailed Description Text (25):

At step 804, the device driver and a bus driver operate in accordance with the method of FIG. 7 to modify configuration memory to include the new unit directory. Further, at step 805, the device driver and bus driver again cooperate to cause a bus reset, thereby forcing other nodes residing on the serial bus to enumerate the modified configuration memory. Steps 806 and 807 are essentially identical to steps 705 and 706, respectively.

## Detailed Description Text (26):

FIG. 9 illustrates a method that may be beneficially applied to a system of devices coupled together via a serial bus. The method of FIG. 8 is preferably implemented, where appropriate, as computer-executable software instructions executed by the appropriate devices within the system. Steps 901 through 903 are essentially equivalent to steps 803 through 805, respectively, and are preferably carried out by a first personal computer or the like coupled to the serial bus. Furthermore, in an embodiment of the present invention, at least one other computer is coupled to the first computer via the serial bus. Referring to the example of FIG. 2, the computer 201, rather than being coupled to the printer 212, could instead be coupled to another computer implementing a 1394-compliant node.

## ABSTRACT:

Information stored in configuration memory of a first device coupled to a communication bus is exposed to other devices allowing the other devices to ascertain the functionality of the first device. A device driver corresponding to the device can, through an interface, cause a bus driver to alter the contents of the configuration memory thereby changing what information is exposed to other devices. When another device "enumerates" the now-altered configuration memory, the other device will learn of the new functionality and proceed in a normal fashion by loading those drivers necessary to use the newly-added functionality. Conversely, when a device and its corresponding device driver is removed, configuration memory is updated accordingly. The present invention may be beneficially applied to systems adhering to the IEEE 1394 Serial Bus standard.

TITLE: Information processing apparatus and method

# Brief Summary Text (9):

In case of <u>serial bus</u> interface adapted to or based on the IEEE1394 standard (hereinbelow, simply referred to as a "1394 interface"), each <u>device</u> holds a <u>node-unique</u> ID as <u>device</u> identification means. The ID is 64-bit data where higher 24 bits indicate a maker ID of the <u>device</u> allocated by the IEEE (the Institute of Electrical and Electronics Engineers), and the lower 48 bits indicate a unique ID that the maker can freely set. Accordingly, regardless of the maker and model of the <u>device</u>, a specific <u>node-unique</u> ID is set in the <u>device</u>. By this <u>device</u> identification means, <u>devices</u> can be specified in data communication on a network using the IEEE 1394 <u>serial bus</u> where a plurality of <u>devices</u> are connected (hereinbelow, referred to as a "1394 network"). Further, display means for recognizing a plurality of <u>devices</u> by using <u>node</u> unique IDs and displaying <u>device</u> connection information in the network called a topology map, may be provided to manage status of use of the 1394 network and improve usefulness of the network.

## Detailed Description Text (9):

The connection among the respective <u>devices</u> may be made by mixedly using the daisy-chain and <u>node</u>-branching methods, thus attaining high connecting freedom. Further, the <u>devices</u> respectively have an ID, and construct a network within a range connected via the 1394 <u>serial bus</u> by recognizing the IDs with each other. For example, the <u>devices</u> respectively play a relaying role if they are daisy-chain connected respectively with a single 1394 <u>serial bus</u> cable, thus constructing a network.

# Detailed Description Text (41):

In FIG. 5, the remaining area is called "unit space", used for designating addresses where information unique to each <u>node</u> such as identification information of each <u>device</u> (vendor name, model name or the like) and use conditions is stored. FIG. 10 shows addresses and functions of the information stored in a <u>serial bus device</u> register in the unit space. FIG. 10 show the addresses by offsets from "0xFFFFF0000800".

## Detailed Description Text (51):

A <u>node</u> that has detected a change in the network connection construction, i.e., the increment/decrement of the number of <u>nodes</u> due to e.g. connection/removal of network <u>device</u> or power ON/OFF operation, or a <u>node</u> that must newly recognize the network connection construction transmits a bus reset signal via the 1394 interface onto the 1394 serial bus.

# <u>Detailed Description Text</u> (123):

In the present embodiment, in a network using the 1394 serial bus, function information including device unique information is stored into the configuration ROMs of the respective devices connected to the network. Then, the functions of the devices are displayed utilizing the function information stored in the configuration ROMs, in accordance with purposes. Further, a service as application software, to search and determine a connection destination device can be easily realized.

## ABSTRACT:

In a 1394 network where a number of devices are connected, it is not easy to specify corresponding between a displayed device and a real device. Accordingly, "selection-candidate update processing, to find a new device and "processing for displaying candidates meeting set conditions" to display candidates which meet set conditions are provided, so as to display a device list window displaying selection candidates in a case where a set condition is, e.g., "printer".

DOCUMENT-IDENTIFIER: US 6643714 B1

TITLE: Modification and use of configuration memory used during operation of a serial bus

Brief Summary Text (5):

Serial buses are well known in the art. A recently developed serial bus standard is the so-called IEEE 1394 serial bus standard, based largely upon the internationally adopted ISO/IEC 13213 (ANSI/IEEE 1212) CSR Architecture Specification and the IEEE 1394-1995 Serial Bus Specification, the teachings of which are herein incorporated by these references. A typical serial bus having an IEEE 1394 standard architecture is comprised of a multiplicity of nodes that are interconnected via point-to-point links, such as cables, that each connect a single node of the serial bus to another node of the serial bus. The nodes themselves are addressable entities which can be independently reset and identified. Nodes are associated with respective components of the computer system and serve as interfaces between the components and the communications links. Nodes are logical entities, each with a unique address. In a preferred implementation, each node provides a so-called configuration ROM (read-only memory)--hereinafter referred to as configuration memory--and a standardized set of control registers that can be accessed by software residing within the computer system.

TITLE: Method of and apparatus for verifying reliability of contents within the configuration ROM of IEEE 1394-1995 devices

## Brief Summary Text (8):

Each node on the IEEE 1394-1995 serial bus provides an identification or configuration read only memory (ROM) in either a minimal or general format. The minimal ROM format includes a single quadlet (4 bytes) of data and provides only a twenty-four (24) bit company identifier. The general ROM format provides other information in addition to the company identifier. The company identifier is used to uniquely identify vendors that manufacture or specify components that are compatible with the IEEE 1394-1995 standard.

# Detailed Description Text (5):

While any appropriate device can implement a <u>node</u>, serve as a host system and display the graphical user interface, an exemplary computer system 18 implementing such a <u>node</u> is illustrated in FIG. 6. Preferably, the host system of the present invention is coupled to an IEEE 1394-1995 <u>serial bus</u> network. However, it should be apparent to those skilled in the art that the <u>node</u> of the present invention can be configured to couple to any appropriate bus or <u>network</u> structure. The computer system 18 includes a central processor unit (CPU) 20, a main memory 30, a video memory 22 and an IEEE 1394-1995 interface circuit 28, all coupled together by a conventional bidirectional system bus 34. The interface circuit 28 includes a <u>configuration ROM</u> 29 and a physical interface circuit 42 for sending and receiving communications on the IEEE 1394-1995 <u>serial bus</u> network. The physical interface circuit 42 includes ports which are preferably each configured to be coupled to IEEE 1394-1995 cables connected to other devices. The physical interface circuit is coupled to a television 46 by the IEEE 1394-1995 <u>serial bus</u> cable 45 and to a video camera 44 by the IEEE 1394-1995 <u>serial bus</u> cable 43.

# ABSTRACT:

A graphical user interface is used to display contents of a configuration memory and includes a hierarchical window illustrating directories and entries within the configuration memory including the relationships between the directories and entries and a data window for displaying data stored within the configuration memory and signalling errors corresponding to the data. The errors are determined by processing the data being displayed to determine a reference value for each entry within the data and to determine if any offset value, pointer value and count value included within any entry references a memory location outside of a boundary of the memory. The reference value specifies a number of times each entry is referenced. Errors are signalled within the data window by displaying entries corresponding to errors in a first color and entries which do not include errors in a second color. The system further includes a bus structure node circuit for coupling the system to other devices over a bus structure. Appropriate headings of directories and entries are displayed with the data in the data window. The bus structure is preferably an IEEE 1394-1995 serial bus.

TITLE: System for retrieving configuration information from node configuration memory identified by key field used as search criterion during retrieval

# Abstract Text (1):

A computer system comprises a plurality of <u>nodes</u> interconnected by point-to-point links and forms a <u>serial bus</u>. Upon system initialization, the bus is scanned and device-specific identification information is retrieved from command and status <u>configuration ROMs</u> associated with each of the plurality of <u>nodes</u>. In one embodiment, a search routine is used to retrieve the device specific information. The search routine begins with the definition of an iterator which is used as a place holder during the search. A simple search begins at the root directory of a hierarchical tree data structure and continues until all directories within the tree have been searched. In more complex embodiments, search relationships (i.e., direction) parameters are defined. Search criteria such as <u>node</u> spec.sub.-- ID and software version numbers are specified and the search is commenced. The search continues until all matching device specific information entries have been returned. The device specific information can be used to load and configure associated drivers for <u>nodes</u>.

# Detailed Description Text (14):

For an embodiment conforming to the IEEE 1394 <u>Serial Bus</u> Standard, each transaction capable <u>node</u> 12, 15, 16, 24, 32, 34, 40 and 44 of the <u>serial bus</u> implements a <u>configuration ROM</u>. The <u>configuration ROM</u> is a nonvolatile memory which stores critical boot information which is accessed during bus initialization as described below. The boot information is stored in the Name Registry and used to identify the appropriate driver software to be loaded for the node of interest.

# Detailed Description Text (15):

FIG. 3 illustrates the general ROM format for each configuration ROM 50 of the serial bus. For one embodiment, the node configuration ROMs 50 reside within the address space of the serial bus in accordance with the IEEE 1394 Serial bus Standard. As shown, the configuration ROM 50 is divided into a root directory 52, various root dependent directories 54, root leafs 56, unit directories 58, unit dependent directories 60, and unit leafs 62. Thus, the directories are arranged in a hierarchical fashion. Within this structure, directories may have "children", "parents" and "siblings".

## Detailed Description Text (17):

All directories in the node configuration ROMs 50 have the format shown in FIG. 4. The directory length parameter specifies the number of following quadlet entries in the directory. Each directory entry then has the format shown in FIG. 5. Each directory entry is broken down into a key field and an entry value field. The key field itself has two fields: the key type, indicating the type of directory entry, and the key value, specifying the particular directory entry, e.g., spec.sub.-- ID, unit software version, etc. The key type definitions for a preferred embodiment according to the IEEE 1394 Serial Bus Standard are shown in Table 1, below.

## Detailed Description Text (18):

For an immediate entry, the entry value is the 24-bit value for that directory entry. Its meaning is dependent on the type of entry. For an offset entry, the entry value contains a 24-bit offset field. The offset value specifies a CSR address as a

quadlet offset from the base address of the initial register space. For the leaf and directory entries, the entry value provides a 24-bit indirect offset value which specifies the address of the leaf or directory of the indirect space. The indirect offset value indirectly specifies the ROM offset address of the leaf or the directory. Thus, using the key type and key value, a specific entry in the configuration ROM 50 of a node on the serial bus can be identified.

## Detailed Description Text (19):

The present invention provides a method for searching the <u>configuration ROMs</u> 50 of the <u>nodes on a serial bus</u>. In one embodiment, a method of searching for and retrieving <u>node</u> software version and spec.sub.-- ID information is provided. This information can then be used by computer system 5 to load appropriate driver software for the nodes of the bus.

## Detailed Description Text (20):

The search routine, in one embodiment, is provided with a pointer to the CSR configuration ROM of a specified node within the address space of the serial bus. Search parameters are defined. The search parameters correspond to the key types and key values defined for the node software version number and spec.sub.-- ID. Using these parameters, the search routine scans the address space of the configuration ROM and returns with matches for the given search parameters.

## ABSTRACT:

A computer system includes a plurality of nodes, each having an associated unique identification and bus address, interconnected by point-to-point links. Device data records are maintained in a memory of the computer system wherein node unique identifications, which are bus reset invariant, are associated with corresponding node bus addresses, which are subject to change with bus resets. A driver associated with a source node initiates a bus transaction and specifies a reference identification for the destination node. The reference identification of the destination node is used to access the device data records to obtain the corresponding destination node bus address. When a bus transaction cannot be completed because a bus reset occurs, the device data records are updated to associate the new bus addresses of the nodes with the corresponding node unique identifications. The new destination node bus address is used to complete the bus transaction that was interrupted by the bus reset.
